F03G 1/02

characterised by shape or material of spring, e.g. helical, spiral, coil

Definition statement

This place covers:

Spring-motors characterised by shape or material of spring.

Spring-motors with cup springs, membrane springs, ring springs or gas springs.

Spring-motors with nanosprings.

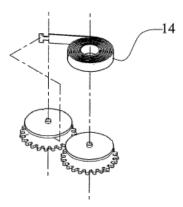

F03G 1/022

{using spiral springs}

Definition statement

This place covers: Spring-motors with spiral springs.

Illustrative example of subject matter classified in this group, note spiral spring 14:

Special rules of classification

The expression "coil spring" can refer either to a spiral spring ($\underline{F03G 1/022}$) or to a helical spring ($\underline{F03G 1/024}$). Search and classify according to the respective embodiments and the specific spring geometry concerned.

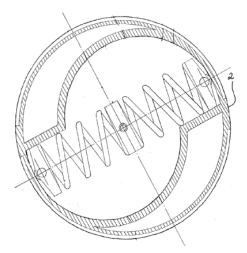

F03G 1/024

{using helical springs}

Definition statement

This place covers: Spring-motors with helical springs.

Illustrative example of subject matter classified in this group:

Special rules of classification

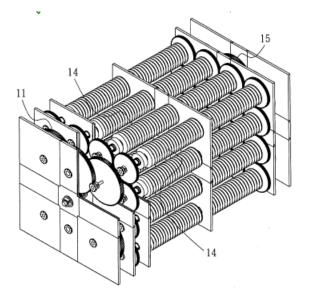

The expression "coil spring" can refer either to a spiral spring ($\underline{F03G 1/022}$) or to a helical spring ($\underline{F03G 1/024}$). Search and classify according to the respective embodiments and the specific spring geometry concerned.

F03G 1/026

{using torsion springs}

Definition statement

This place covers: Spring-motors with torsion springs.

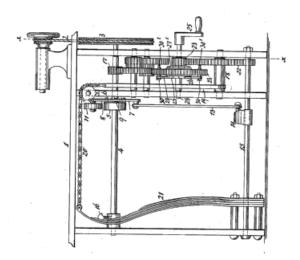

F03G 1/028

{using leaf springs}

Definition statement

This place covers: Spring-motors with leaf-springs.

Illustrative example of subject matter classified in this group:

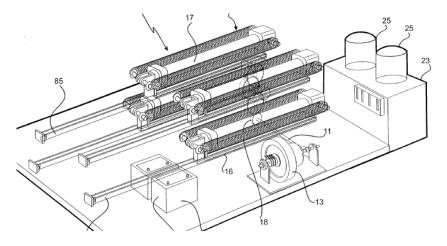

F03G 1/029

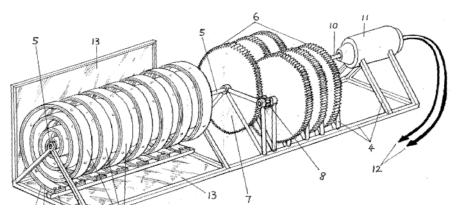

{using two or more springs}

Definition statement

This place covers:

Spring-motors with two or more springs, e.g. spiral springs or leaf springs or combinations thereof and being connected for example in series or parallel.

F03G 1/032

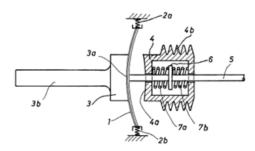

{using bimetals}

Definition statement

This place covers:

Spring-motors applying bimetals.

Illustrative example of subject matter classified in this group:

F03G 1/04

using rubber springs

Definition statement

This place covers: Spring-motors with rubber springs.

FIG. 2 FIG. 3 FIG. 3

Illustrative example of subject matter classified in this group:

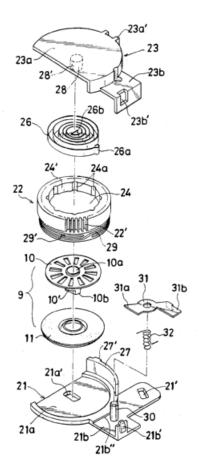

F03G 1/06

Other parts or details

Definition statement

This place covers:

Other parts or details of spring-motors, e.g. speed-control, decoupling or damping mechanisms thereof.

F03G 1/08

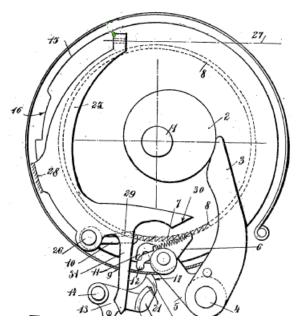

for winding

Definition statement

This place covers:

Other specific parts or details for winding of spring-motors.

Illustrative example of subject matter classified in this group:

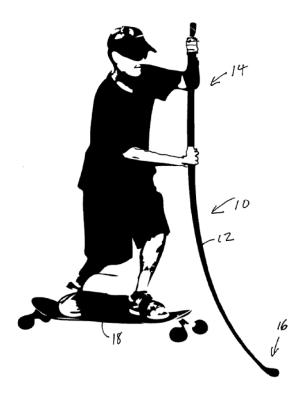

F03G 1/10

for producing output movement other than rotary, e.g. vibratory

Definition statement

This place covers:

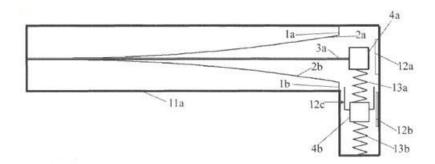

Other parts or details of spring-motors for producing output movement other than rotary, e.g. vibratory.

Illustrative example of subject matter classified in this group:

The illustrative example above shows a propulsion device (10) which includes an elongated pole (12) made of flexible and elastic material such as carbon fibre. A first end (14) of the pole (12) is formed to be suitable for grasping by a human hand. The second end (16) may be formed to be suitable for placing on a firm surface for propelling a wheeled vehicle such as a skateboard (18).

Illustrative example of subject matter classified in this group:

Reference is made to the beam 3a and the movement up and down by moving masses.

F03G 3/00

Other motors, e.g. gravity or inertia motors

Definition statement

This place covers:

Motors driven by gravity or inertia force, e.g. driven by solid falling bodies like bowls, or by solid falling materials like sand, or by out of balance bodies like pendulums, or by the change of the orientation of the rotation axis of a rotating body.

References

References out of a residual place

Limiting references

This place does not cover:

Using solid falling bodies	F03G 3/02
Using sand or the like	F03G 3/04

F03G 3/091

{using unbalanced wheels}

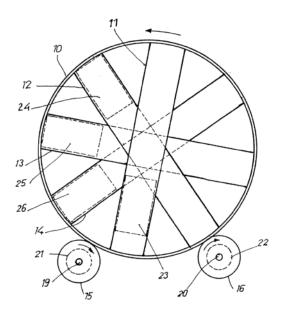

Definition statement

This place covers:

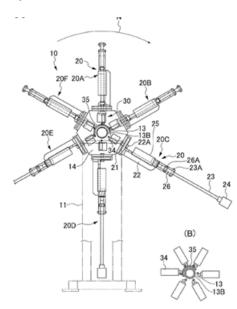

The wheel unbalance and thus the wheel rotation is generated by moving the gravity point of one or several masses within the wheel between a position close to the wheel rotation axis and a position far from the wheel rotational axis. For the movement of the mass or masses, a specific input of energy is required.

F03G 3/091 (continued) Definition statement

The following illustration shows a device for converting mechanical energy into electrical energy, in which a weight (23-26) is arranged so as to be periodically displaceable by mechanical, hydraulic or pneumatic means against the direction of gravity, in which further at least one duct (11-14) extending in a diametral direction and arranged in a circular frame rotatable about its middle transverse axis is provided. In this arrangement the frame (10) is drive connected at the circumference to at least one electrical generator (21, 22).

The following illustration shows a rotary device of the unbalanced wheel type with weights actuated by hydraulic motors.

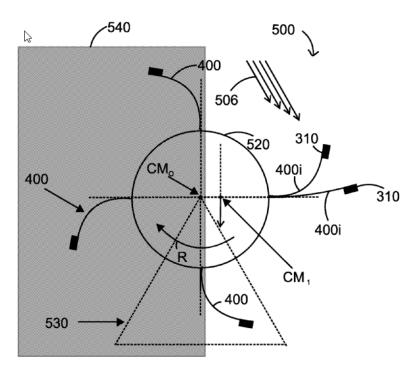

Relationships with other classification places

If the movement of the gravity point of the respective mass or masses is effected by solar energy, only FO3G 6/O02 is to be considered.

The following illustration shows a solar-powered device (500) that includes a central hub (520); plural curved blades (400) attached to the central hub (20); and plural weights (310) connected to the plural curved blades (400). A curved blade (400i) of the plural curved blades (400) has a proximal end attached to the central hub (520) and a distal end attached to a corresponding weight (310), and

wherein the curved blade (400i) is made of a material that changes its geometry when exposed to solar energy.

F03G 3/094

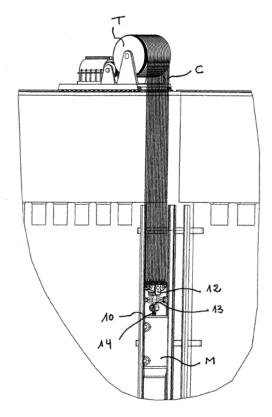

{specially adapted for potential energy power storage stations; combinations of gravity or weight motors with electric motors or generators}

Definition statement

This place covers:

The potential energy previously stored in a weight is converted into rotational energy, in particular for driving a generator, e.g. during high demand of electricity, by moving down the weight. The process is reversed, e.g. during low demand of electricity and the generator is used as an electric motor that rotates a shaft and shifts up the respective weight.

Devices for producing mechanical power from geothermal energy

References

Informative references

Attention is drawn to the following places, which may be of interest for search:

Geothermal collectors	<u>F24T 10/00</u>

Glossary of terms

In this place, the following terms or expressions are used with the meaning indicated:

Steam	Water in the gas phase
Vapour	Substance, not being steam, in the gas phase
Working fluid	The fluid that converts heat into mechanical work in a turbine
Source fluid	The fluid in thermal contact with the geothermal well. This fluid is either in direct fluid and thermal contact with the well or only in thermal contact with the well.

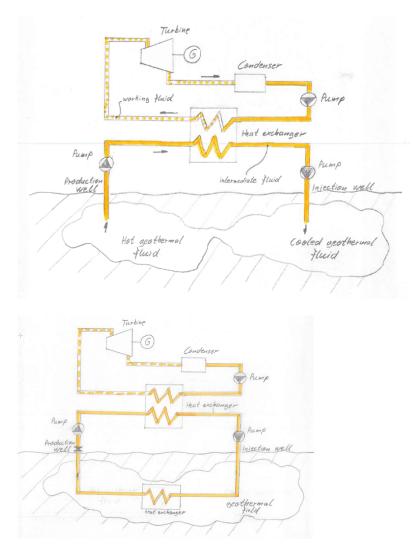

Rankine Cycle	During conversion of heat into mechanical work, a phase change of the working fluid is involved.
Brayton cycle	Open or closed thermodynamic cycle of a constant pressure heat engine, e.g. of the gas turbine
Stirling Cycle	Closed, reversible and regenerative thermodynamic cycle with a gaseous working fluid

{Binary cycle plants where the source fluid from the geothermal collector heats the working fluid via a heat exchanger}

Definition statement

This place covers:

Binary cycle plants whereby the source fluid is in contact with the geothermal well and whereby the working fluid forms separate circuits that are thermally connected to each other via a heat exchanger.

with direct {working} fluid contact

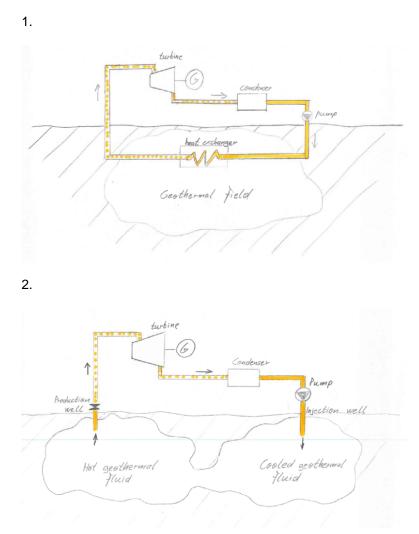

Definition statement

This place covers:

Single-cycle plants where the source fluid is the working fluid.

In such a single cycle power plant there is only one fluid cycle. This implies that the source fluid extracting the heat from the geothermal well and the working fluid typically driving a steam turbine are the same.

In this place, it is not relevant if the source fluid as such is in direct contact with the geothermal well rock or not. In this place, the source fluid can be either in direct contact with the rock or could flow through a piping that is only in thermal exchange with the rock.

{characterised by the geothermal collectors}

Definition statement

This place covers:

The geothermal collector with the source fluid is in contact with the geothermal well.

F03G 4/026

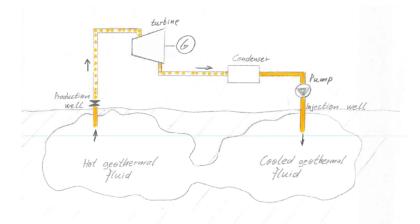

{open loop geothermal collectors}

Definition statement

This place covers:

The source fluid in the geothermal collector is in fluid contact with the geothermal well.

Illustrative example of subject matter classified in this group:

F03G 4/029

{closed loop geothermal collectors, i.e. the fluid is pumped through a closed loop in heat exchange with the geothermal source, e.g. via a heat exchanger}

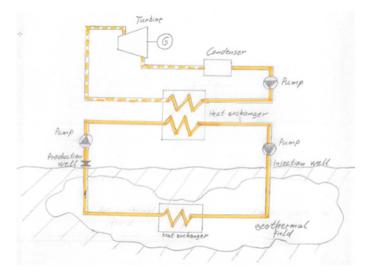

Definition statement

This place covers:

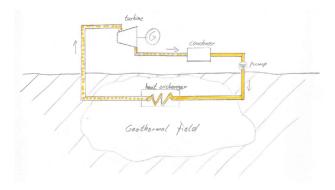

Closed-loop geothermal collectors. The source fluid flows through a piping that is in thermal exchange with the rock. There is no direct contact between the source fluid and (dry) rock in the geothermal well.

In this place, both closed-loop geothermal collectors being part of a binary-cycle-type ($\underline{F03G 4/001}$) as well as of a single-cycle-type geothermal power plant ($\underline{F03G 4/02}$) are covered.

1. Closed-loop geothermal collector of the binary-cycle type

2. Closed-loop geothermal collector of the single-cycle type

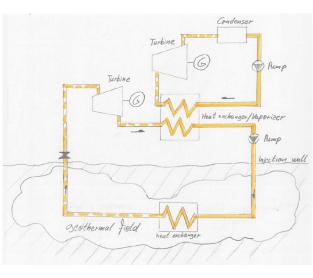

F03G 4/031

{using waste heat from a primary power cycle to produce mechanical power in a second cycle}

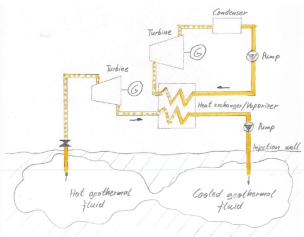

Definition statement

This place covers:

There are at least two working fluid circuits, which are fluidically separated but thermally connected via a heat exchanger.

Illustrative example of subject matter classified in this group:

F03G 4/033

{having a Rankine cycle}

Definition statement

This place covers:

The working fluid being subject to a phase change from liquid to vapour, e.g. water turning to steam.

F03G 4/035

{of the Organic Rankine Cycle [ORC] type or the Kalina Cycle type}

Definition statement

This place covers:

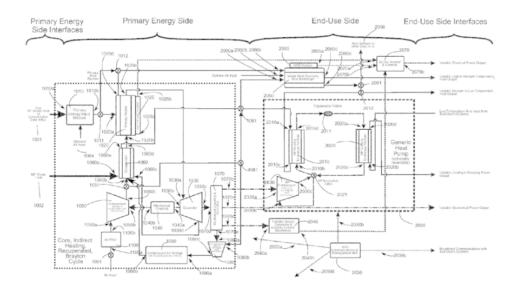

An Organic Rankine Cycle uses an organic fluid, like CFC, HFC, HC, PFC, with a boiling point lower than the water boiling point.

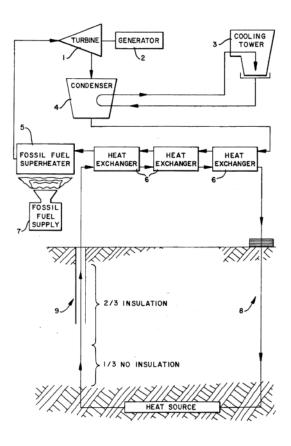

In a Kalina cycle, the conversion of heat into mechanical power is realized by using a solution of two fluids with different boiling points, the most widely used combination being water and ammonia.

{having other power cycles, e.g. Stirling, transcritical or supercritical cycles; combined with other power sources, e.g. wind, gas or nuclear}

Definition statement

This place covers:

Relationships with other classification places

For combined geothermal power and solar power plants, search and classification in <u>F03G 4/037</u> and <u>F03G 6/0055</u> applies.

F03G 4/045

F03G 4/069

{characterised by the brine or scale treatment, e.g. brine desalination, scale deposit prevention or corrosion-proofing}

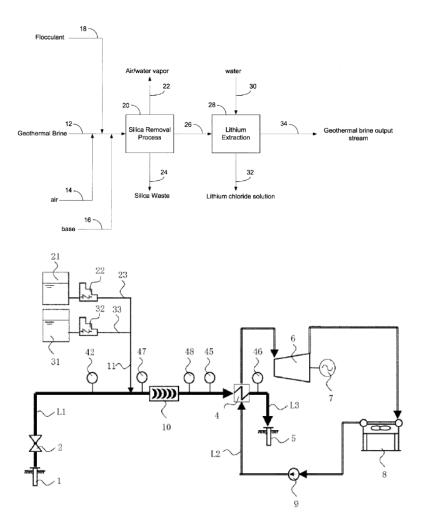

Definition statement

This place covers:

Treatment of accumulating brine (salt-water) or scale (chalky deposit caused by water evaporation).

Definition statement

The following example shows a method for producing geothermal power using geothermal brines while producing a reduced silica and iron brine having improved injectivity. The resulting compositions include a composition with reduced silica, iron, and lithium having reduced quantity of total suspended solids.

Method for inhibiting scale and geothermal power generating device

F03G 4/072

{Controlling or monitoring}

Definition statement

This place covers: Control or monitoring of geothermal power plants.

F03G 4/074

{Safety arrangements}

Definition statement

This place covers:

Safety arrangements of geothermal power plants.

F03G 5/00

Devices for producing mechanical power from muscle energy (driving cycles **B62M**)

Definition statement

This place covers:

Devices for producing mechanical power from human or animal muscle energy and being of the endless-walk type, e.g. treadmills, or other than of the endless-walk type, e.g. pedal generators.

References

References out of a residual place

{of the motor-generator type, e.g. the generator is also usable as an electric motor}

Definition statement

This place covers:

Devices for producing mechanical power from muscle energy other than of endless-walk type driven by humans and having a combined motor-generator.

Illustrated is an electric bike with capability of self-charging. The electric bike is fixedly supported by supporting legs so as to be operated in a stationary point. A user steps on a petal assembly of the electric bike to drive a wheel to rotate. The electric bike further includes a power-generating device, a controller, a battery and a damper. The controller is used to receive a power source outputted by the power-generating device and convert the power source into a plurality of DC power sources to charge the battery. The damper consumes a portion of electricity generated by the power-generating device. With the above arrangement, the electric bike can be charged by itself while the user is exercising.

Special rules of classification

Documents dealing with solar power plants with a Rankine cycle that do not mention if the solar rays are concentrated or not are to be classified only under <u>F03G 6/003</u> (single working fluid circuit) or <u>F03G 6/005</u> (binary cycle plants with a heating fluid and a working fluid).

{of the Organic Rankine Cycle [ORC] type or the Kalina Cycle type}

Definition statement

This place covers:

Devices for producing mechanical power from solar energy having an Organic Rankine cycle or a Kalina cycle and without means for concentrating the solar rays, e.g. solar collectors. There is only one fluid circuit for the collectors and the turbine.

An Organic Rankine cycle uses an organic fluid, like CFC, HFC, HC, PFC, with a boiling point lower than the water boiling point.

In a Kalina cycle, the conversion of heat into mechanical power is realized by using a solution of two fluids with different boiling points, the most widely used combination being water and ammonia.

F03G 6/005

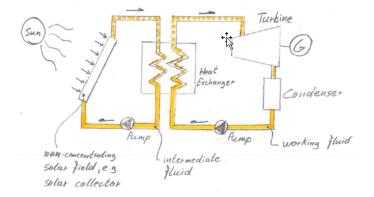

{Binary cycle plants where the fluid from the solar collector heats the working fluid via a heat exchanger}

Definition statement

This place covers:

Devices for producing mechanical power from solar energy having a Rankine cycle and without means for concentrating the solar rays, e.g. with solar collectors. There are at least two fluid cycles involved (i.e. binary cycle). The heating fluid, sometimes also called the intermediate fluid, e.g. water or a molten salt, is the fluid transporting the heat from the solar field to at least one heat exchanger, e.g. a preheater or vaporizer, the heat exchanger transferring the heat to the separate working fluid cycle. The working mechanical/electrical power. The Rankine cycle refers to the working fluid circuit.

Illustrative example of subject matter classified in this group:

F03G 6/0055

{having other power cycles, e.g. Stirling or transcritical, supercritical cycles; combined with other power sources, e.g. wind, gas or nuclear}

Definition statement

This place covers:

Devices for producing mechanical power from solar energy without solar concentration and having non-Rankine power cycles.

Relationships with other classification places

For combined geothermal power and solar power plants, search and classification in <u>F03G 4/037</u> and <u>F03G 6/0055</u> applies.

using a single state working fluid

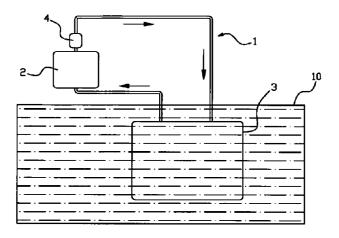

Definition statement

This place covers:

Devices for producing mechanical power from solar energy using a single state working fluid, e.g. air or ammonia gas, with or without means for concentrating solar rays and with or without an intermediate fluid for heat transfer.

Illustrative example of subject matter classified in this group:

The following illustration showing an apparatus for generating electricity by using solar energy is provided. The main structure includes a circulation pipeline 1 and a hydroelectric generator 4. The circulation line 1 is filled with water or other convective water. The circulation line 1, partially submerged below the sea surface 10, is partially exposed above the sea surface 10. A portion of the circulation pipeline 1 submerged below the sea surface 10 forms a cooling water tank 3. A portion of the circulation pipeline 1 exposed above the sea surface 10 forms a heat-absorbing water tank 2 whose outer circumference is covered with a heat-absorbing layer. A water outlet is formed above the heat absorbing water tank 2, and a water inlet is formed below. A water turbine generator 4 is provided near the water outlet of the heat-absorbing water tank 2.

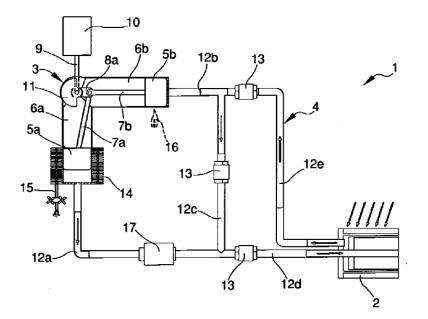

gaseous {(F03G 6/064, F03G 6/068 take precedence)}

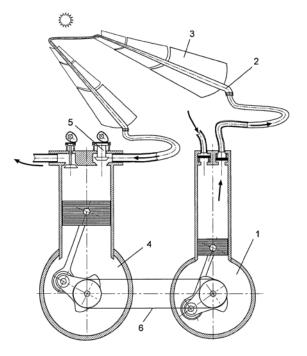

Definition statement

This place covers:

Devices for producing mechanical power from solar energy using a gaseous working fluid, e.g. a Stirling cycle, with or without means for concentrating solar rays and with or without an intermediate fluid for heat transfer.

Illustrative example of subject matter classified in this group:

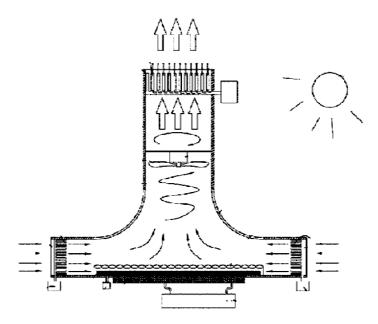

{by producing an updraft of heated gas or a downdraft of cooled gas, e.g. air driving an engine}

Definition statement

This place covers:

Solar up-wind tower power plants in the form of chimneys.

F03G 6/065

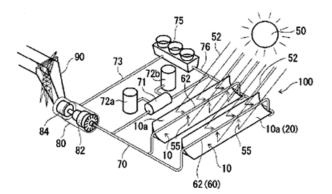

{having a Rankine cycle}

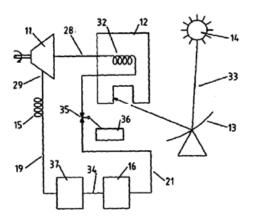

Definition statement

This place covers:

Devices for producing mechanical power from solar energy having a Rankine cycle and with means for concentrating the solar rays, e.g. parabolic linear or point concentrators. There is only one fluid circuit between the collectors and the turbine.

F03G 6/066

{of the Organic Rankine Cycle [ORC] type or the Kalina Cycle type}

Definition statement

This place covers:

Devices for producing mechanical power from solar energy having an Organic Rankine cycle or a Kalina cycle and with means for concentrating the solar rays, e.g. parabolic linear or point concentrators. There is commonly only one fluid circuit between the collectors and the turbine.

An Organic Rankine cycle uses an organic fluid, like CFC, HFC, HC, PFC, with a boiling point lower than the water boiling point.

In a Kalina cycle the conversion of heat into mechanical power is realized by using a solution of two fluids with different boiling points, the most widely used combination being water and ammonia.

F03G 6/067

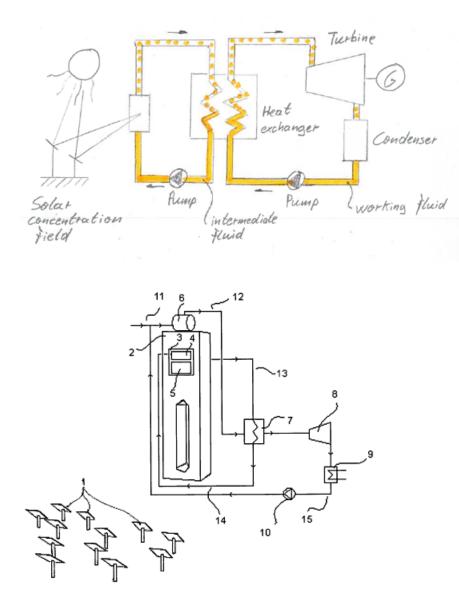

{Binary cycle plants where the fluid from the solar collector heats the working fluid via a heat exchanger}

Definition statement

This place covers:

Devices for producing mechanical power from solar energy having a Rankine cycle and with means for concentrating the solar rays, e.g. with parabolic linear or point concentrators. There are at least two fluid cycles involved (i.e. binary cycle). The heating fluid, sometimes also called the intermediate fluid, e.g. water or a molten salt, is the fluid transporting the heat from the solar field to at least one heat exchanger, e.g. a preheater or vaporizer, the heat exchanger transferring the heat to the separate working fluid cycle. The working fluid is the fluid used in a working machine, e.g. a steam turbine, to generate the mechanical/electrical power. The Rankine cycle refers to the working fluid circuit.

F03G 6/083

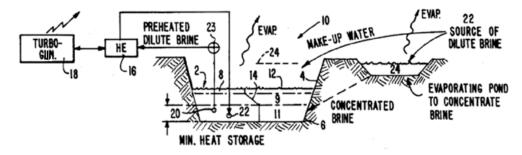

{with solar ponds}

Definition statement

This place covers:

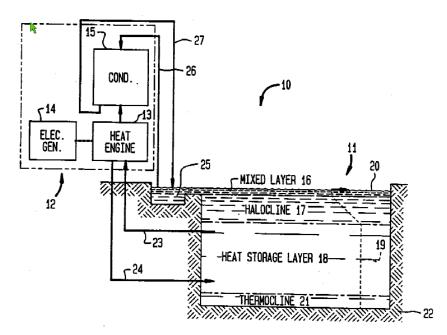

Devices for producing mechanical power from solar energy with solar ponds for collecting the solar energy.

Illustrative example of subject matter classified in this group:

Waste salts and brines are disposed of by constructing salt water solar pond power plants, concentrating the waste salts and brines, and then introducing them into the heat storage layers of the solar ponds of the power plants. The basins in which such solar ponds are constructed are made deeper than needed to sustain operation of the power plant at its designed output, and after a deep basin is filled, the concentrated brine from the heat storage layer is available to construct another solar pond which is then available for storing additional waste salts. In concentrating the waste salts, sodium

chloride will precipitate, and this material can be deposited at the bottom of the solar ponds to seal the same against leakage.

{Over-night operation}

Definition statement

This place covers:

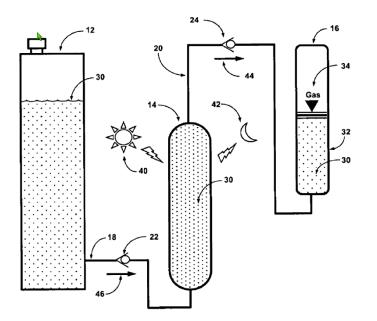

Features specifically related to the over-night operation of solar power plants.

Illustrative example of subject matter classified:

The figure above illustrates a solar chimney, comprising an enclosure defining a path for flow of a fluid to be heated, the enclosure containing a heat exchanger, a solar collector located outside the enclosure, a reservoir for storing a heat transfer fluid, and means for directing heat transfer fluid between the reservoir, the solar collector, and the heat exchanger, wherein, in a first position of the directing means, appropriate for use during daytime, heat transfer fluid can flow from the reservoir, then into the heat exchanger, and then back to the reservoir, and wherein,

in a second position of the directing means, appropriate for use during nighttime, heat transfer fluid can flow from the reservoir, into the heat exchanger, and then back to the reservoir.

The figure above illustrates a thermal pump system energized by a daytime heating phase and a night time cooling phase associated with a naturally occurring environmental heating and cooling cycle that includes a hydraulic fluid source, a thermal fluid expansion chamber having a fixed internal volume, and a hydraulic accumulator at least partially filled by a compressible gas. A first unidirectional flow valve connected to a first duct permits flow only out of the hydraulic fluid source during the night time cooling phase. A second unidirectional flow valve connected to a second duct permits flow only out of the thermal fluid expansion chamber upon expansion of the hydraulic fluid trapped in the thermal fluid expansion chamber upon expansion of the hydraulic fluid trapped in the thermal fluid expansion chamber has a thermally conductive wall communicating thermal energy from the naturally occurring heating and cooling cycle to the hydraulic fluid trapped in the fixed internal volume.

F03G 7/003

{Motors driven by thermophoresis or thermodiffusion}

Definition statement

This place covers:

Illustrative example of subject matter classified:

The figure above illustrates a device that generates an oriented flux of gas molecules and utilises said oriented flux for obtaining electric energy. The device comprises a housing (2) containing gas, a membrane (3) dividing the housing into compartments, wherein the membrane (3) is provided with a plurality of funnel-like through holes (6), a bypass (7) that links the said compartments, a turbine machine (8) with an electric current generator (9), arranged within the bypass (7), and a heat exchanger (10) supplying heat to the first compartment (4). Owing to the configuration of the holes in the membrane, the number of molecules that penetrate from the first compartment (4) to the last compartment (5) exceeds the number of molecules that return from the last compartment (5) to the first compartment (4). Due to the difference in pressures in the compartments, the gas flux flows through the bypass (7) and generates electricity by means of turbine machine (8) and the generator.

Glossary of terms

In this place, the following terms or expressions are used with the meaning indicated:

Thermophoresis or	Different particles in a mixture of mobile particles exhibit different
Thermodiffusion	responses to the force of a temperature gradient.

{characterised by the actuating element (actuating elements for mechanical power producing mechanism using expansion or contraction of bodies due to heating, cooling, moistening, drying or the like F03G 7/061)}

Definition statement

This place covers:

Illustrative example of subject matter classified in this group:

An actuation apparatus includes at least one magnetic shape memory (MSM) element containing a material configured to expand and/or contract in response to exposure to a magnetic field. Among other things, the MSM element may be configured to pump fluid through a micropump by expanding and/or contracting in response to the magnetic field. The magnetic field may rotate about an axis of rotation and exhibit a distribution having a component substantially perpendicular to the axis of rotation. Further, the magnetic field distribution may include at least two components substantially

orthogonal to one another lying in one or more planes perpendicular to the axis of rotation. The at least one MSM element may contain nickel, manganese, and gallium. A polymerase chain reaction (PCR) may be enhanced by contacting a PCR reagent and DNA material with the MSM element.

Special rules of classification

Actuating elements for mechanical power producing mechanisms using expansion or contraction of bodies due to heating, cooling, moistening, drying or the like to be classified in $\frac{F03G}{7/061}$.

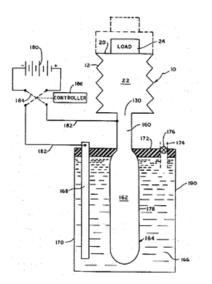

F03G 7/011

{Actuators having a material for absorbing or desorbing a gas, e.g. with a fuel cell reaction or a metal hydride}

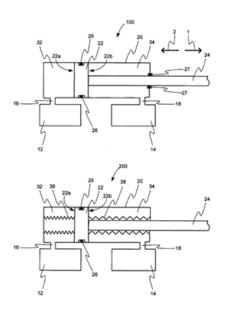

Definition statement

This place covers:

Illustrative example of subject matter classified in this group:

The illustrative example above shows an actuator incorporating an electrolytic gas generatorevacuator is disclosed. A membrane of material selectively permeable to a drive gas is inserted in a combined inlet-outlet of an expandable chamber. The membrane forms a portion of an electrolytic cell by being immersed in a body of electrolyte capable of transporting an ionic species of the drive gas between the membrane as one electrode and a counter electrode. By connecting the combined inletoutlet of the chamber to the outside surface of the membrane and cyclically driving the electrolytic cell in a drive gas generation mode and a drive gas evacuation mode, the chamber will cyclically expand and contract.

The illustrative example above shows a metal hydride actuator.

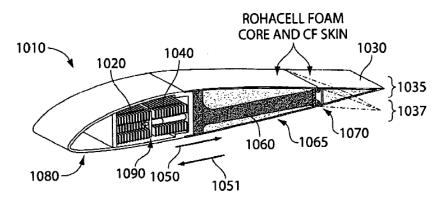

F03G 7/012

{Electro-chemical actuators}

Definition statement

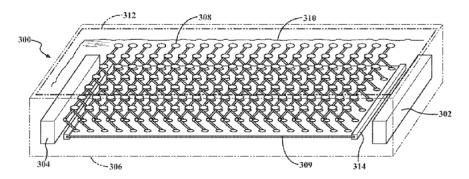

This place covers:

Illustrative example of subject matter classified in this group:

Illustrated is a device involving electrochemical actuation. The devices may comprise at least one component capable of exhibiting a volumetric or dimensional change upon application of a voltage. The volumetric or dimensional change may produce mechanical work. The devices may be capable of exhibiting high actuation rates and supporting high amounts of stress (e.g., in tensile and/or

compressive loading). The device may provide morphing structures that may be useful in applications such as airfoils.

Illustrated is a protein array for converting chemical energy into mechanical energy.

F03G 7/0121

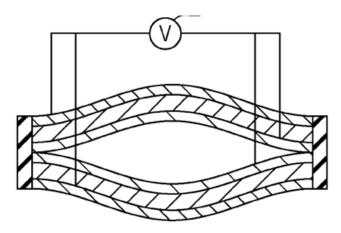

{Electroactive polymers}

Definition statement

This place covers:

Electroactive polymers not otherwise provided for, e.g. polymers with carbon nanotubes, ionic or responsive gels, integrated polymer metal composites (IPMC), like nafion or flemion.

Illustrative example of subject matter classified in this group:

An expansion and contraction actuator has a first long actuator portion and a second long actuator portion that face each other and connection members that connect the long sides of each of the first long actuator portion and the second long actuator portion to each other, in which a part of the first long actuator portion and a part of the second long actuator portion are apart from each other to thereby form a hollow structure; the first long actuator portion and the second long actuator portion each have a pair of long electrodes and a long electrolyte layer having an electrolyte, long internal electrodes thereof are the same cathode or anode electrodes, long external electrodes thereof are counter electrodes thereto, and the actuator expands and contracts in the direction of the screw axis by voltage application.

{pumping or compressing fluids, e.g. microfluidic devices}

Definition statement

This place covers:

Illustrative example of subject matter classified in this group:

An actuation apparatus includes at least one magnetic shape memory (MSM) element containing a material configured to expand and/or contract in response to exposure to a magnetic field. Among other things, the MSM element may be configured to pump fluid through a micropump by expanding and/or contracting in response to the magnetic field. The magnetic field may rotate about an axis of rotation and exhibit a distribution having a component substantially perpendicular to the axis of

rotation. Further, the magnetic field distribution may include at least two components substantially orthogonal to one another lying in one or more planes perpendicular to the axis of rotation. At least one MSM element may contain nickel, manganese, and gallium. A polymerase chain reaction (PCR) may be enhanced by contacting a PCR reagent and DNA material with the MSM element.

F03G 7/027

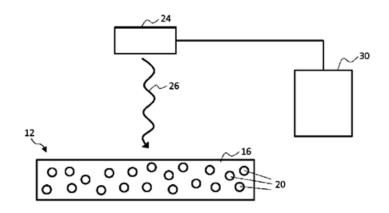

{Control or monitoring}

Definition statement

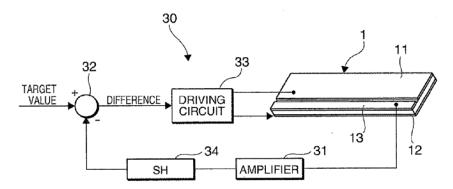

This place covers:

Illustrative example of subject matter classified in this group.

Control or monitoring related features of mechanical-power-producing devices not otherwise provided for.

An electroactive material actuator device is provided having a controllable stiffness profile. An actuator member of the device comprises an electroactive polymer material having light absorbing filler elements embedded or contained therein. The light absorbing filler elements are adapted to absorb and convert incident light energy to heat energy to therefore heat surrounding sections of the electroactive material. By selectively controlling an intensity level or spectral composition of a light source directed at the actuator member, a specific degree and spread of heating can be achieved across the member and, as a result, a specific desired stiffness or flexibility profile realised across the body of the actuator member.

Illustrated is an actuator, and more particularly, the configuration of an actuator which can detect a direction of displacement or an amount of displacement.

{Safety arrangements}

Definition statement

This place covers:

Safety arrangements related features of mechanical-power-producing devices not otherwise provided for.

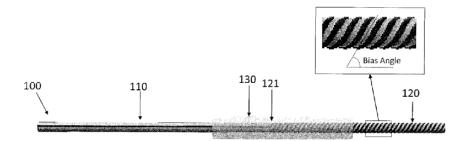

F03G 7/029

{characterised by the material or the manufacturing process, e.g. the assembly}

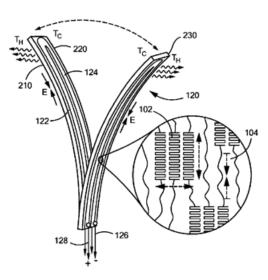

Definition statement

This place covers:

F03G 7/045

{Environmental heat plants or OTEC plants using an Organic Rankine Cycle [ORC] or a Kalina Cycle}

Definition statement

This place covers:

Environmental heat plants using pressure or thermal differences occurring in nature or ocean thermal energy conversion (OTEC) plants using an Organic Rankine Cycle (ORC) or a Kalina cycle.

An Organic Rankine cycle uses an organic fluid, like CFC, HFC, HC, PFC, with a boiling point lower than the water boiling point.

In a Kalina cycle the conversion of heat into mechanical power is realized by using a solution of two fluids with different boiling points, the most widely used combination being water and ammonia.

F03G 7/047

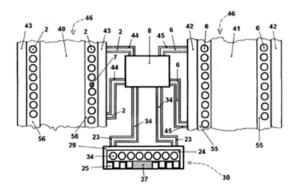

{Environmental heat plants or OTEC plants using heat pumps}

Definition statement

This place covers:

Environmental heat plants using pressure or thermal differences occurring in nature or ocean thermal energy conversion (OTEC) plants using heat pumps.

Illustrative example of subject matter classified in this group:

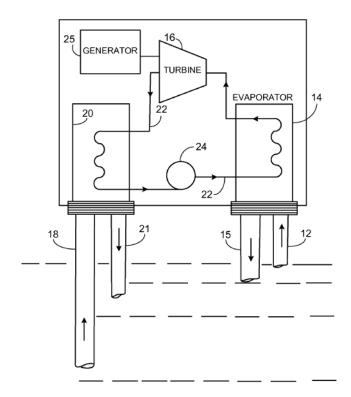

The figure above illustrates a cooling electric energy generator with Stirling engine (46) integrated in it that absorbs heat energy from environment through external heat collector (30), and it concentrates heat energy on heat side of Stirling engine (46) by internal heat pump device (8). Internal heat pump device (8) cools cold side of Stirling engine (46) as well as it absorbs heat energy from cool side and it concentrates heat energy on heat side of Stirling engine (46). Internal heat pump device (8) is initially started with electric energy from external generator. Stirling engine (46) starts rotation in electric generator (48), which further supplies internal heat pump devices (8), through programmed switcher. Heat energy from environment and from cold side of Stirling engine (46) is four to nine time higher quantity than electric energy necessary for functioning internal heat pump device (8).

Ocean thermal energy conversion, i.e. OTEC

Illustrative example of subject matter classified in this group:

Device for generating driving force with a middle disc held in a cage-like manner by ropes between two coaxially mounted side discs, which is transferred into an unstable equilibrium position by moistening a rope under the then effective tensile force and achieves rotary motion, characterised in that the central disc (5) holding ropes (8, 9 and 10, 11) are guided as holding ropes in these side discs (4, 4 ') and are connected to lever-like tendons (18,18') mounted on these side discs, on the one hand, to which on the other side, the ropes (16, 16"), alternately subjected to moistening and drying, engage.

{characterised by the actuating element}

Definition statement

This place covers:

Mechanical-power-producing mechanisms or actuators, not otherwise provided for, characterised by the actuating element, e.g. thermal or humidity actuation.

Illustrative example of subject matter classified in this group:

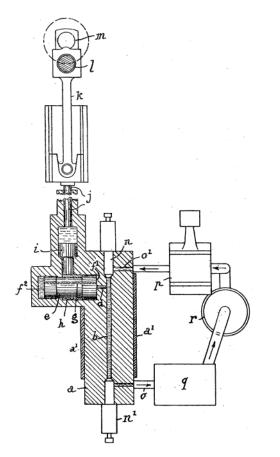

Illustrated is an evaporation-driven engine comprising a water source having a high humidity zone proximate a surface of the water source, a supporting structure and a hygroscopic material disposed on the supporting structure and configured to generate mechanical force in response to a changing relative humidity, wherein the hygroscopic material is repeatedly exposed to the high humidity zone and removed from high humidity zone thereby causing the hygroscopic material to generate mechanical force.

{using the thermal expansion or contraction of enclosed fluids}

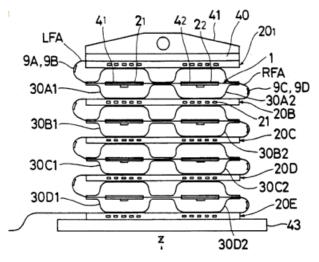

Definition statement

This place covers:

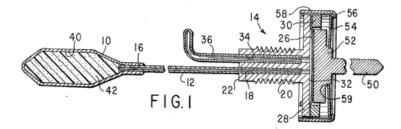

Illustrative example of subject matter classified in this group:

This invention relates to motors of the kind in which motion is produced by transmitting to a piston the expansion of a liquid due to the heating thereof in a temporarily closed space surrounded by a continuously heated body, said space having an inlet and outlet closable by valves, and wherein the expanded heated liquid is displaced through said outlet by the introduction of cold liquid through said inlet, the displaced liquid being led through a cooling device prior to being utilised again in the heated working space.

An actuator is composed of a plurality of three-dimensionally arranged containers each of which is constructed into deformable configuration and each of which is set to accommodate therein an amount of expandable fluid in response to the increase of the temperature, a heat supply device for supplying the heat to the fluid in each of the containers, a cooling device for cooling the fluid in each of the containers and a control device for controlling the heat supply device and the cooling device.

The invention relates to fluid pressure responsive devices and, in particular, to devices employing a member which is movable by a fluid pressure and volume change, such as fluid expansion and contraction in response to changes in temperature.

{the fluids subjected to phase change}

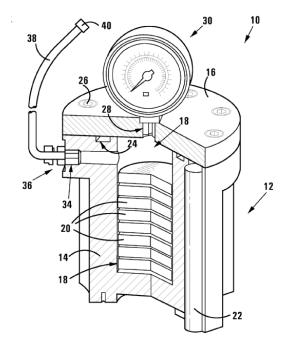

Definition statement

This place covers:

The enclosed fluid changes its phase when heated/cooled, e.g. wax actuators, liquid crystal actuators, low melting point alloy actuators, melting polymer actuators.

Illustrative example of subject matter classified in this group:

A piston (14) is slidably received in a chamber (10). The chamber is filled with an expandable medium (16), such as wax that expands and contracts significantly as it undergoes a phase change from a solid to a liquid state. A Peltier effect chip (20) selectively adds and removes heat energy from the chamber, hence the medium, to cause the medium to change phase. A temperature control (26) maintains the temperature of the medium substantially at the phase change temperature such that the addition of heat causes an isothermal melting (hence, expansion) and the removal of heat causes an isothermal solidification (hence, contraction). The chamber defines a plurality of thin branches such that the heat is transferred more effectively.

{using the thermal expansion or contraction of solid materials}

Definition statement

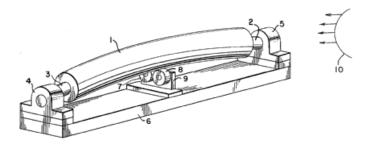

This place covers:

Illustrative example of subject matter classified in this group:

The illustration above shows a ratcheting micromotor with a ratchet bar defining ratchet teeth along an edge thereof, and first and second ends in opposition to one another. The first end is adapted to be coupled to an object to be moved. A spring is coupled on one end thereof to the second end of the ratchet bar and adapted to be fixed at another end thereof to a base. A bidirectional actuator configured for linear movement in one of a first direction and a second direction, and when energized has a common yoke coupled to a central portion thereof for movement in correspondence therewith.

The common yoke includes teeth formed along an edge and positioned such that its teeth engage a portion of the ratchet teeth. A control system energizes the bidirectional actuator to move, alternately, in the first direction and the second direction.

The illustration above shows a motor comprising a rotor supported to rotate freely about its longitudinal axis while the axis is confined to an elastically bowed configuration by internal or external means. Heat, cold or other stress inducing means applied to the side of the rotor causes local internal stresses that cause the rotor to rotate in the direction that allows relaxation of the induced stress.

{using shape memory elements}

Definition statement

This place covers:

Illustrative example of subject matter classified in this group:

The actuator comprises a strand of shape memory material having a length that is variable between a first length corresponding to an undeformed state and a second length corresponding to a state of lengthwise deformation. The strand is arranged to return to the undeformed state when it is heated to a predetermined temperature. The strand comprises a fixed end and a mobile end arranged to move between a first and a second position when the variable length of the SMM strand changes. The actuator further comprises a heating wire coiled around the strand for heating the strand, the coiled heating wire forming a circular helix, the uniform slope of which is selected so as to avoid any substantial change of the arc length of the circular helix caused by the strand changing its length.

{Wires}

Definition statement

This place covers:

Shape memory elements using wires.

Illustrative example of subject matter classified in this group:

An SMA (scalable multi-element shape memory alloy) actuator is arranged to tilt the mirror in a zoom camera to effect optical image stabilization. The actuator may comprise four angled-V SMA wires. The actuator may alternatively comprise a gimbal flexure and SMA wires. In this case, there may be four SMA wires or two SMA wires and two springs. The SMA wires may be straight wires or wires hooked in a V shape.

F03G 7/06145

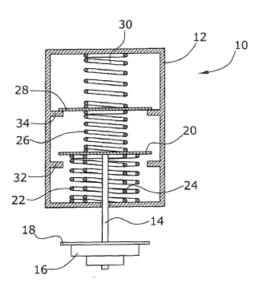

{Springs}

Definition statement

This place covers:

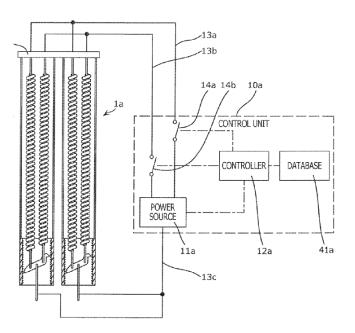

Shape memory elements using springs.

Illustrative example of subject matter classified in this group:

Actuators are known for operating a control element, with a control element (14) which is fastened to a force-transmitting member (20), an opening spring (26) made of a shape memory alloy which acts on the force-transmitting member (20) in a first direction, the spring force being dependent upon the

temperature of the opening spring (26), and a restoring spring (22) which acts on the force-transmitting member(20) in a direction opposite to the first direction. In order to prevent unwanted opening at ambient temperatures above the structure conversion temperature, according to the invention, a closing spring (24) made of a shape memory alloy acts on the force-transmitting member (20) in a direction opposite to the first direction.

The present disclosure relates to an actuator and an actuator set that stretch or contract in accordance with a change in temperature.

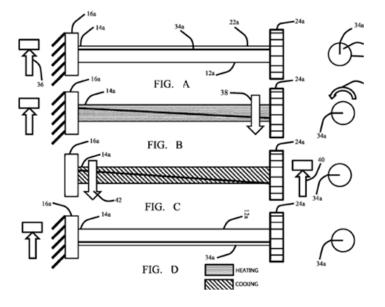

F03G 7/06146

{Torque tubes or torsion bars}

Definition statement

This place covers:

Shape memory elements using torque tubes or torsion bars.

Illustrative example of subject matter classified in this group:

A scalable multi-element shape memory alloy (SMA) rotary motor employs a plurality of SMA tubes. A ratcheting gear transmission couples the plurality of SMA tubes in parallel to a common output. A controller provides power to a plurality of heaters associated with each of the plurality of SMA tubes, sequentially heating selected heaters to provide continuous rotational motion of the common output.

The illustration above shows a rotation-type actuator actuated by temperature fluctuation or temperature gradient and energy harvesting device using same.

{Clamping, fixing or crimping parts}

Relationships with other classification places

Illustrative example of subject matter classified in this group:

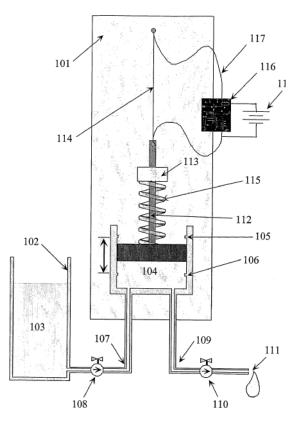

Wellbore devices for use in filtration, wellbore isolation, production control, lifecycle management and wellbore construction may include at least a first and a second shape-memory material each having an altered geometric position and each an original geometric position. Each shape-memory material may include a polyurethane material held in the altered geometric run-in position at a temperature below glass transition temperature (Tg), where the Tgs and/or the respective slope changes of the first and second polyurethane materials are different. Once the wellbore device is in place downhole and the first and second shape-memory materials are subjected to temperatures above their Tgs, the materials will deploy and expand to recovered geometric positions at or near their original geometric positions to perform their filtration, isolation, control or other function. These deployments or expansions may occur at different times or rates.

{for pumping or compressing fluids}

Relationships with other classification places

Illustrative example of subject matter classified in this group:

Pump useful for subcutaneous, long-term, automated drug delivery has actuator including shape memory alloy material to drive movable member from first to second position as the shape memory alloy material goes through dimensional change.

{Motors following new scientific theories not otherwise provide for, e.g. using quantum field effects like zero-point energy, Casimir effect}

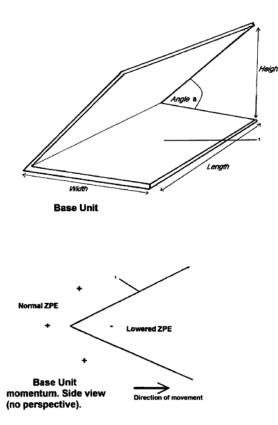

Definition statement

This place covers:

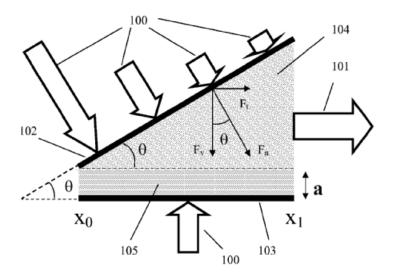

Illustrative example of subject matter classified in this group:

In the illustration above, a force cell provides propellant-less propulsion for linear thrust applications and fuel-less torque for rotary applications. Linear thrust applications include propulsion for aircraft, spacecraft, flying cars, construction equipment for use in low and zero gravity environments, stabilization for ultra-high buildings and realization of ultra-long unsupported spans. Rotary torque applications include engines to drive electric generators of all sizes—from mobile phone size to power station size. Force cells use radiation pressure originating from the zero-point fields in the vacuum of space—the force in the Casimir effect, to produce a macroscopic external force through use of a multiplicity of microscopic Casimir cavities consisting of wedge shaped non-charged conducting plates attached to a matrix of non-conducting material. Force cells arranged in balanced pairs can produce modulated external thrust. Force cells arranged circularly can produce modulated torque.

The illustration above shows two conducting plates are joined at an angle to produce a Vee or wedge shape of nanometer scale. It is claimed that this can use zero-point energy to produce a propulsive (Casimir) force or drive a machine such as a generator. The device may comprise a plurality of wedges in a zigzag shape, and may have a smooth plate ^ attached to one side, which is claimed to give rise to an asymmetric force. It is also claimed that the device, when positioned wholly or partly surrounding an object, can reduce the mass of the object.

The illustration above shows methods, microstructures and devices for generating a transverse Casimir force by using an array of non-parallel conducting plates and an intervening dielectric or semiconductor material to provide propulsion in manned or unmanned space vehicles.

{harvesting energy from inertia forces}

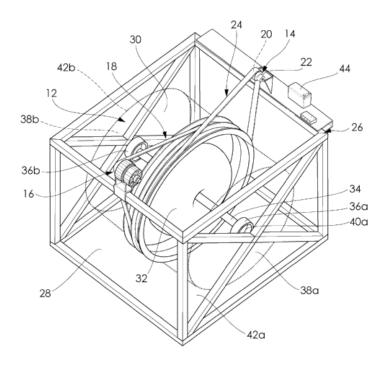

Definition statement

This place covers:

Illustrative example of subject matter classified in this group:

The illustration above shows an electrical generator for generating electrical energy from the kinetic energy associated with a rotating body, designed in the form of a heavy wheel. The generator includes a vertical cylindrical container housing a rotor float supported by a central attachment and a quantity of liquid in the space between the container and the rotor float. The rotor float includes a cover from which bars made from metal or another heavy metal extend, the ends of which bars support a circular ring bearing a non-slip band acted on by electric propulsion motors. In addition, a drive device, such as a ring gear, is associated with the cover and a toothed wheel is meshed therewith, said toothed wheel being associated with the rotation axle of an electrical generator.

Illustrated above is an apparatus for producing energy comprising a flywheel assembly arranged for rotation, drive means operatively coupled to the flywheel assembly, the drive means including biasing means connected to an actuator arranged to bias the biasing means providing stored energy in the biasing means, transmission means coupled between the flywheel assembly and the biasing means

where release of the stored energy in the basing means provides a driving force which drives the transmission means to effect rotation of the flywheel assembly which gains momentum, extraction means operatively coupled to the flywheel assembly for rapid extraction of the momentum of the flywheel assembly as well as an energy generator associated with the extraction means for generating energy from the rapidly extracted momentum of the flywheel assembly.

{Thermodynamic processes}

Definition statement

This place covers:

Illustrative example of subject matter classified in this group:

Method for converting low-grade energy and a fuelless jet engine for carrying out said method

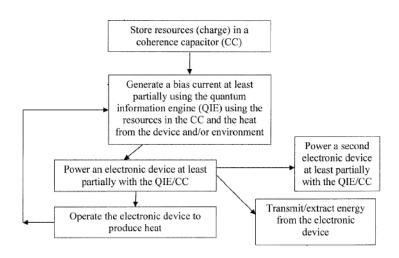

F03G 7/135

{following unproven scientific theories; Theories about perpetual motion}

Definition statement

This place covers:

Illustrative example of subject matter classified in this group:

System for quantum energy storage can include a quantum information engine including topological insulator having at least one edge. A coherence capacitor can include nuclei of atoms within the topological insulator, and each nucleus can have a spin direction. An energy source can be electrically connected to the topological insulator and configured to supply a current along at least one edge of the topological insulator. The current can interact with at least one nucleus of the nuclei to flip a spin direction of the at least one nucleus.
